

Project #14: Bianca Hill and Tom Allen (Decidr, <https://www.decidr.ai/>)

About Decidr: Decidr is an Australian technology company building a business operating system and decision-intelligence platform. This project sits within our Org Self Knowledge workstream (product: Sugarwork), which focuses on capturing organisational knowledge and making it structured, reusable and trustworthy.

Title: Assessing the Credibility of Organisational Knowledge from Fragmented Data

Description:

Organisations hold knowledge across people, documents, communications and operational systems. Having information is not the same as that information being credible.

Evidence is often incomplete, outdated, copied from another source, or contradicted by what actually happens. The open question is how to judge, transparently, what an organisation can defensibly claim to know.

Students will design and test an explainable framework for assessing the credibility of organisational knowledge claims from fragmented, imperfect evidence. Working from a prepared dataset representing a small organisation, they will identify knowledge claims — for example, "Finance approves all customer discounts above 15%" — connect each claim to its supporting and contradicting evidence, and develop a method for judging how credible the claim is and how confident the organisation should be in it.

Core research question: given multiple, incomplete and potentially conflicting data points, how should the credibility of an organisational knowledge claim be assessed?

There is no single correct answer. Some claims should remain unresolved where the evidence is insufficient. The value lies in the transparency, calibration and defensibility of the approach.

Approach and skills:

Teams may take different technical paths — information retrieval, knowledge graphs, probabilistic or Bayesian methods, LLM-assisted analysis, statistical modelling, or hybrids — provided the result is transparent and explainable.

- Core: Python and data analysis; text analysis; working with structured and unstructured data; statistical evaluation and visualisation; clear documentation of assumptions and methodology.
- Developable during the project: LLMs, embeddings and retrieval-augmented generation; information retrieval and entity matching; probabilistic or Bayesian reasoning; confidence calibration and sensitivity analysis; explainable machine learning; knowledge graphs.

What Decidr provides:

A prepared dataset — synthetic and/or anonymised, combining text and structured records with deliberate gaps, contradictions and provenance to reason about — released in phases, with a small labelled development set at kickoff. A project lead available for regular check-ins and feedback. A limited NDA covering non-public conceptual material; students' technical methods and general learnings remain theirs to present.

What students gain:

A substantive applied-research problem at the frontier of decision intelligence. Real experience in evidence assessment, confidence calibration and explainability. Exposure to how a growing Australian platform company thinks about organisational knowledge.

Engagement:

Autumn 2026 semester, 12 August – 21 October. Multiple student teams are welcome; different framings of the same problem are encouraged. Students will not be asked to judge whether the organisation is well run, connect to live systems, or work with Decidr's proprietary data model.
